

Single top quark production in CMS

Matthias Komm*, on behalf of the CMS collaborations

Imperial College London (UK)

E-mail: Matthias.Komm@cern.ch

In this note, latest cross section measurements of single top production in the three main production modes, s -channel, W-associated, and t -channel, by the CMS collaboration are presented using proton-proton collision data at centre-of-mass energies of 7, 8, and 13 TeV.

39th International Conference on High Energy Physics (ICHEP)
04-11 July, 2018
Seoul, Korea

*Speaker.

1. Introduction

The single top quark production processes are excellent probes to test the predictions of electroweak interactions at the scale of the top quark mass and beyond. Inclusive single top quark cross section measurements can be used to infer the absolute value of the CKM matrix element V_{tb} in a model-independent manner whereas ratios of top quark over antiquark production cross sections are sensitive to the parton distribution function (PDF). In the following recent measurements of single top quark production via the s channel, W-associated, and t -channel are presented.

2. s channel

The single top quark s -channel production mode has the smallest cross section amongst the three processes. It has been measured using pp collision data recorded by the CMS experiment at centre-of-mass energies of 7 and 8 TeV [1]. Events containing one isolated electron or muon and two or three jets of which one or two are b-tagged have been analysed. By performing a simultaneous maximum likelihood (ML) fit the the distribution of a Boosted Decision Tree (BDT) discriminant a signal strength of $\sigma_{s\text{-ch.}}^{\text{meas.}} / \sigma_{s\text{-ch.}}^{\text{theo.}} = 2.0 \pm 0.9$ is obtained. This result corresponds to an observed (expected) significance of 2.5 (1.1) standard deviations.

3. W-associated production

The cross section of producing a single top quark in association with a W boson has been measured at 13 TeV in events containing one isolated muon and one isolated electron together with one or two jets [2]. The signal yield is estimated by performing a ML fit to the distributions of a BDT discriminant in 1j1b and 2j1b regions (shown in Fig. 1) and to the transverse momentum of the subleading jet in the 2j2b control region where the latter allows an in-situ constraint of the jet energy scale. A cross section of 63.1 ± 1.8 (stat) ± 6.4 (syst) ± 2.1 (lumi) pb is found which agrees well with the predicted cross section of 71.7 ± 1.8 (scale) ± 3.4 (PDF) pb calculated at approximate next-to-next-to-leading order [3].

4. t channel

The production of single top quarks via the t channel does not occur charge-symmetric in pp collisions. The charge ratio, $R = \sigma_{t\text{-ch.}}(t)/\sigma_{t\text{-ch.}}(\bar{t})$, depends on the valence quark composition of the proton since an up quark in the initial state leads to the production of a top quark whereas a down quark would yield a top antiquark instead. A corresponding analysis [4] is performed using events containing an isolated muon or electron together with two or three jets of which one or two are b-tagged. The distributions of a BDT discriminant for top quark and antiquark events are used to infer the charge ratio through an ML fit. A charge ratio of $R = 1.65 \pm 0.02$ (stat) ± 0.04 (syst) is found which is compared in Fig. 2 to the predictions of various PDF sets. The inclusive cross section has been measured as well and found to be 219.0 ± 1.5 (stat) ± 33.0 (syst) pb which is well in agreement with the next-to-leading order prediction of $217.0^{+9.0}_{-7.7}$ (scale + PDF + α_s) pb [5].

Figure 2: Comparison of the measured charge ratio in t -channel single top quark production with the predictions by various PDF sets. The figure is taken from Ref. [4].

A first measurement of differential single top quark cross sections in the t channel has been performed as well [6]. Following a similar event selection as the presented t -channel measurement above, the cross section is estimated in intervals of the reconstructed top quark transverse momentum and rapidity through an ML fit to the distribution of a BDT discriminant. The resulting cross sections, shown in Fig. 3, are found to be in agreement with the prediction by various generators within uncertainties.

5. Conclusion

Recent measurements of single top quark production via the three main production modes, s channel, W-associated, and t -channel, by the CMS collaboration have been presented. Proton-proton collision data recorded at centre-of-mass energies of 7, 8, and 13 TeV have been analysed. Overall the results are found to be in agreement with the predictions.
